³ Technische Universität Dresden, Germany

Abstract. We show that occurrences of the universal quantifier in the left-hand side of general concept inclusions can be rewritten into $\mathcal{EL}^{++}$ axioms under certain circumstances. I.e., this intuitive modeling feature is available for OWL EL while retaining tractability. Furthermore, this rewriting makes it possible to reason over corresponding extensions of $\mathcal{EL}^{++}$ and Horn-SROIQ using standard reasoners.

1 Introduction

“All OWLED 2004 paper were written by George Lucas.”

The sentence just given is vacuously true since the OWLED conference series was established in 2005, i.e., the statement is about the empty set: There are no OWLED 2004 papers, hence all of them (namely, none) were written by George Lucas.

Vacuously true statements arise from the formal semantics under which the universal quantifier is interpreted in first-order predicate logic (and, more generally, in most of mathematics and computer science). This formal semantics gives rise to a neat mathematical theory (e.g., the universal quantifier is then just the dual of the existential quantifier), but at the same time this reading of the universal quantifier remains rather unintuitive and also an educational obstacle in the teaching of logic-based methods. In the Semantic Web realm, this was e.g. prominently pointed out in [13], but examples of course abound.

Natural language use often does not intend vacuous truth. If John says “all my children are adopted,” then we assume that he does in fact have children, all of which are adopted. If we later found out that he never had any children, then we may assess that he was lying earlier, rather than understand that his statement was vacuously true.

More formally speaking, and in terms of description logic modeling, our intuitive understanding would be that John belongs to the class

$$(\forall \text{hasChild. AdoptedPerson}) \cap (\exists \text{hasChild. AdoptedPerson}),$$

rather than simply $\forall \text{hasChild. AdoptedPerson}$ which would seem more similar to the natural language sentence on the syntax level. For lack of a better word, we call such an occurrence of a universal a witnessed universal.
The observations just given are of course not at all new. And in fact, from a formal logical perspective the observations do not even appear to be very interesting at first sight: A witnessed universal simply seems to be syntactic sugar because it can be expressed using a conjunction of a universal and an existential.

However, it turns out that the discussion becomes much more interesting in the context of logics – in this case description logics of course – where the use of universal quantifiers is restricted in some way, i.e., for Horn Description Logics and for some of the tractable OWL Profiles. Indeed, a version of witnessed universal was investigated in [11] where it was shown that adding left-hand side witnessed universals to Horn-SROIQ does not increase the data complexity. The result was shown by a rather involved argument using a modification of the SROIQ tableau algorithm.

However, we noticed that it is not necessary to modify the underlying reasoning algorithm, but that instead a simple knowledge base transformation can be applied with which reasoning can be reduced to the case of knowledge bases without universals. As a result, it is possible to add left-hand side witnessed universals to OWL EL while retaining tractability. While we will later provide a formal definition and correctness proof for the transformation, let us already give an example which explains the rewriting. We want to model the statement that a Pizza all of which toppings are vegetarian, is in fact a vegetarian Pizza. Note, though, that the axiom \( \forall \text{hasTopping}.\text{VegTopping} \sqsubseteq \text{VegPizza} \) does not sufficiently capture the intended meaning, since a Pizza without any toppings (i.e., dough only) does hardly qualify as a Pizza in most people’s minds. An adequate axiomatization thus seems to be

\[
\text{Pizza} \sqcap (\forall \text{hasTopping}.\text{VegTopping}) \sqcap (\exists \text{hasTopping}.\text{VegTopping}) \sqsubseteq \text{VegPizza}
\] (1)

where the left-hand side does not suffer from the just mentioned vacuous truth issue.

The rewriting which we introduce in this paper now rewrites this axiom into the three axioms

\[
\text{Pizza} \sqcap (\exists R_{\text{Pizza}}.\text{hasTopping}) \sqcap (\exists R_{\text{Pizza}}.\text{VegTopping}) \sqsubseteq \text{VegPizza}
\]

where \( R_{\text{Pizza}} \) is a fresh role name. These axioms are expressible in \( \mathcal{ELH} \).

So in this paper, we report on this transformation, its correctness, and some of its consequences. The plan of the paper is as follows. We first introduce some formal preliminaries in Section 2. Then, in Section 3 we show our transformation and prove it correct. We then make a proposal for an OWL/RDF and functional style syntax for witnessed universals in Section 4 before we conclude in Section 5.

\[1\] The conference presentation given for this paper was actually what made us start thinking about the topic.
2 Preliminaries

In the following paragraphs we formally introduce the syntax, terminology and semantics of the description logics $\mathcal{EL}^{++}$ and Horn-\textit{SROIQ} as required for the paper. We assume a certain familiarity with the topic and refer the reader to the literature \cite{13} if further background is required. To improve the readability of the paper and the clarity of our formal arguments we make use of succinct normal forms to describe the syntax of the aforementioned description logics. This is without loss of generality: polynomial algorithms to normalize $\mathcal{EL}^{++}$ and Horn-\textit{SROIQ} ontologies can be found in \cite{7,8}.

A \textit{DL signature} is a tuple $\langle \mathbf{N}_C, \mathbf{N}_R, \mathbf{N}_I \rangle$ where $\mathbf{N}_C$, $\mathbf{N}_R$, and $\mathbf{N}_I$ are finite (but large enough) disjoint sets of \textit{concept names}, \textit{role names} and \textit{individuals} such that $\{\bot, \top\} \subseteq \mathbf{N}_C$. For the rest of this paper we assume that a signature $\Sigma$ has been fixed and so omit further references to it.

Let $\mathbf{N}_R \cup \{R^- \mid R \in \mathbf{N}_R\}$ be the set of \textit{roles}. Roles that are not elements of $\mathbf{N}_R$ are called \textit{inverse roles}. A \textit{concept expression} is a conjunction $C_1 \sqcap \ldots \sqcap C_n$ such that all $C_i$ are of the form $\exists R.A$, $\exists R. \text{Self}$, $\text{ran}(R)$, $\forall R.A$, $\leq 1 R.A$, $A$ or $\{a\}$ where $A \in \mathbf{N}_C$, $R \in \mathbf{N}_R$ and $a \in \mathbf{N}_I$. Concept expressions of the form $\{a\}$ are called \textit{nominals}.

We define a function $\text{Inv}$ that maps every role to its inverse counterpart, as follows.

$$\text{Inv}(R) = \begin{cases} R^-, & \text{if } R \in \mathbf{N}_R \\ S, & R = S^- \end{cases}$$

2.1 Syntax

A \textit{DL axiom} is an expression as depicted in Figure 1. Given a set $\mathcal{O}$ of DL axioms, we define the following notions.

- Let $\sqsubseteq_\mathcal{O}$ be the minimal relation over roles such that $R \sqsubseteq_\mathcal{O} S$ if $R \sqsubseteq S$ or $\text{Inv}(R) \sqsubseteq \text{Inv}(S)$ are in $\mathcal{O}$.
- Let $\sqsubseteq^*_\mathcal{O}$ be the reflexive transitive closure of $\sqsubseteq_\mathcal{O}$.
- Let $\prec_\mathcal{O}$ be the relation over roles such that $R \prec_\mathcal{O} S$ and $\text{Inv}(R) \prec_\mathcal{O} S$ if and only if
  - $R \neq S$,
  - $R \neq \text{Inv}(S)$, and
  - $R \sqsubseteq S$, $R \circ V \sqsubseteq S$ or $V \circ R \sqsubseteq S$ are in $\mathcal{O}$.
- Let $\prec^*_\mathcal{O}$ be the transitive closure of $\prec_\mathcal{O}$.

A role $R$ is \textit{simple with respect to} $\mathcal{O}$ if there is no axiom of the form $T \circ V \sqsubseteq S \in \mathcal{O}$ for every role $S$ such that $S \sqsubseteq^*_\mathcal{O} R$ or $S \sqsubseteq^*_\mathcal{O} \text{Inv}(R)$.

The DL $\mathcal{EL}^{++}$. An \textit{$\mathcal{EL}^{++}$ axiom} is an expression as depicted in the first four columns of Figure 1. An \textit{\mathcal{EL}^{++} ontology} $\mathcal{O}$ is a set of $\mathcal{EL}^{++}$ axioms that satisfies the following conditions.
Fig. 1. DL Axioms. Where \( A(i), B \in \mathbb{N}_C \), \( R, S, V \in \mathbb{N}_R \) and \( a, b \in \mathbb{N}_I \).

1. If \( \exists R.\text{Self} \sqsubseteq B \in \mathcal{O} \), then \( R \) is simple.
2. If \( \{ R \circ V \sqsubseteq S, \text{ran}(S') \sqsubseteq B \} \subseteq \mathcal{O} \) and \( S \sqsubseteq^* S' \) then \( \text{ran}(V) \sqsubseteq B \in \mathcal{O} \).

For a more comprehensive explanation of these restrictions, necessary to preserve tractability of reasoning algorithms, see [2].

The DL Horn-\textit{SROIQ}. A Horn-\textit{SROIQ} axiom is an expression as depicted in Figure 1. A Horn-\textit{SROIQ} ontology \( \mathcal{O} \) is a set of Horn-\textit{SROIQ} axioms that satisfies the following conditions:

1. If \( \exists R.\text{Self} \sqsubseteq B \in \mathcal{O} \) or \( A \sqsubseteq \leq 1 R.B \) are in \( \mathcal{O} \), then \( R \) is simple.
2. The relation \( \prec^* \) is irreflexive.

Condition (2) is commonly referred as role regularity. For a more comprehensive explanation of these restrictions, necessary to preserve decidability of reasoning algorithms, see [5].

Note that we allow for axioms of the form \( A_1 \sqcap \exists R.A_2 \sqcap \forall R.A_3 \sqsubseteq B \) in our definition of \( \mathcal{EL}^{++} \) and Horn-\textit{SROIQ}. These axioms are not usually considered part of the definition of these languages [2,5], and they cannot be normalized away using previous standard techniques.

2.2 Semantics

The semantics of an ontology is given through the definition of an interpretation \( \mathcal{I} = (\Delta^\mathcal{I}, \cdot^\mathcal{I}) \) where \( \Delta^\mathcal{I} \) is a set and \( \cdot^\mathcal{I} \) is a function that maps each individual in the ontology to an element of \( \Delta^\mathcal{I} \), each concept name to a subset of \( \Delta^\mathcal{I} \) and each role name to a binary relation over \( \Delta^\mathcal{I} \). Interpretations are extended to concept expressions as shown in the upper part of Figure 2. We say that an axiom \( \alpha \) is entailed by an interpretation \( \mathcal{I} \), written as \( \mathcal{I} \models \alpha \), if the conditions defined in the lower part of Figure 2 hold. An interpretation \( \mathcal{I} \) satisfies an ontology \( \mathcal{O} \), written as \( \mathcal{I} \models \mathcal{O} \), if \( \mathcal{I} \models \alpha \) for every \( \alpha \in \mathcal{O} \). If this is the case, we say that \( \mathcal{I} \) is a model of \( \mathcal{O} \). An ontology \( \mathcal{O} \) entails an axiom \( \alpha \), written as \( \mathcal{O} \models \alpha \), if \( \mathcal{I} \models \alpha \) for every model \( \mathcal{I} \) of \( \mathcal{O} \).

3 Witnessed Left-Hand Side Universals

We first define our new transformation that rewrites axioms of the form \( A_1 \sqcap \exists R.A_2 \sqcap \forall R.A_3 \sqsubseteq B \) into standard \( \mathcal{EL}^{++} \) (and also Horn-\textit{SROIQ}) axioms.
Conjunction  \[ C_1 \sqcap \ldots \sqcap C_n \]
Existential Restriction  \[ \exists R.A \]
Self Restriction  \[ \exists R.\text{Self} \]
Range Restriction  \[ \text{ran}(R) \]
Universal Restriction  \[ \forall R.A \]
At Most Restriction  \[ \leq 1 \]
Nominal  \[ \{a\} \]
Top  \[ \top \]
Bottom  \[ \bot \]
Role Chain  \[ R \circ V \]
Inverse Role  \[ R \]

Concept Inclusion  \[ C \sqsubseteq D \]
Role Inclusion  \[ R \sqsubseteq S \]
Role Chain Inclusion  \[ R \circ V \sqsubseteq S \]

\[
\begin{align*}
C_1 \sqcap \ldots \sqcap C_n & : C_1 \sqcap \ldots \sqcap C_n \\
\exists R.A & : \{x \mid \exists y : (x,y) \in R^2, y \in D \} \\
\exists R.\text{Self} & : \{x \mid (x,x) \in R^2 \} \\
\text{ran}(R) & : \{x \mid (y,x) \in R \} \\
\forall R.A & : \{x \mid \forall y : (x,y) \in R^2, y \in D \} \\
\leq 1 & : \{x \mid \sharp\{(x,y) \in R^2 \mid y \in A\} \leq 1 \} \\
\{a\} & : \{a^2\} \\
\top & : \Delta^2 \\
\bot & : \emptyset \\
\{x,z\} & : \{(x,z) \mid (x,y) \in R^2, (y,z) \in V^2 \} \\
\{(x,y) \mid (y,x) \in \text{inv}(R)^2 \} & : \{(x,y) \mid (y,x) \in \text{inv}(R)^2 \}
\end{align*}
\]

Fig. 2. Semantics of DL Constructors and Axioms. Where  \( x^i, y, z \in \Delta^2 \), \( C, D \) are concept expressions, \( A \in \mathbb{N}_C \), \( R, S \in \mathbb{R} \), \( a, b \in \mathbb{N}_I \) and \( v \in \mathbb{N}_V \)

**Definition 1.** Let \( \mathcal{O} \) be an \( \mathcal{EL}^{++} \) or Horn-SROIQ ontology. Then \( \mathcal{O}_\varphi \) is the ontology that results from substituting every axiom \( \alpha = A_1 \sqcap \exists R.A_2 \sqcap \forall R.A_3 \sqsubseteq B \in \mathcal{O} \) by axioms \( \exists R.A_2 \sqsubseteq X_\alpha \), \( A_1 \sqcap X_\alpha \sqsubseteq Y_\alpha \), \( Y_\alpha \sqsubseteq Z_\alpha.R \), \( Z_\alpha \sqsubseteq \text{ran}(R) \), \( \exists Z_\alpha.A_3 \sqsubseteq B \) where \( X_\alpha \) and \( Y_\alpha \) are fresh concepts and \( Z_\alpha \) is a fresh role.

We can verify that the transformation removes all universals while the output stays within the base language.

**Lemma 1.** If \( \mathcal{O} \) is an \( \mathcal{EL}^{++} \) (respectively, Horn-SROIQ) ontology, then \( \mathcal{O}_\varphi \) is an \( \mathcal{EL}^{++} \) (respectively, Horn-SROIQ) ontology without universal quantifiers.

**Proof.** It is straightforward to see that the axioms added by the transformation are \( \mathcal{EL}^{++} \) (respectively, Horn-SROIQ) axioms. Also, note that the newly added axioms by the transformation do never violate any of the defining conditions for language membership. In particular, not that a role \( R \in \mathbb{N}_R \) is simple with respect to \( \mathcal{O}_\varphi \) if and only if is simple with respect to \( \mathcal{O} \). Furthermore, note that no axiom of the form \( R \circ V \sqsubseteq S \), \( A \sqsubseteq 1R.B \) or \( \exists R.\text{Self} \sqsubseteq B \) is added by the transformation. \( \square \)

Hence, after the transformation we can always make use of existing reasoning algorithms and tools for the appropriate description logic fragment. Also note that the number of axioms added by the transformation is linear and thus there are no implications for the complexity. Our central technical result is the following.
Theorem 1. $\mathcal{O}$ and $\mathcal{O}_\varphi$ are equisatisfiable.

Proof. We first show how to construct a model $\mathcal{J}$ of $\mathcal{O}_\varphi$ given a model $\mathcal{I}$ of $\mathcal{O}$. Let $\Delta^\mathcal{J} = \Delta^\mathcal{I}$ and $\cdot^\mathcal{J}$ be as follows:

- For every $a \in \mathbb{N}$, $a^\mathcal{J} = a^\mathcal{I}$.
- For every $C \in \mathsf{N}_\mathbb{C}$, $x \in C^\mathcal{J}$ if and only if $x \in C^\mathcal{I}$.
- For every $R \in \mathsf{N}_R$, $(x,y) \in R^\mathcal{J}$ if and only if $(x,y) \in R^\mathcal{I}$.
- For every $\alpha = A_1 \cap \exists R.A_2 \cap \forall R.A_3 \subseteq B \in \mathcal{O}$ and every $x \in (\exists R.A_2)^\mathcal{J}$, $x \in X_\alpha^\mathcal{J}$.
- For every $\alpha = A_1 \cap \exists R.A_2 \cap \forall R.A_3 \subseteq B \in \mathcal{O}$ and every $x \in A_1^\mathcal{I} \cap (\exists R.A_2)^\mathcal{J}$, $x \in Y_\alpha^\mathcal{J}$ and
  - if $x \in (\forall R.A_3)^\mathcal{J}$ then $(x,y) \in Z_\alpha^\mathcal{J}$ for some $y$ such that $(x,y) \in R^\mathcal{J}$,
  - otherwise $(x,y) \in Z_\alpha^\mathcal{J}$ for some $y$ such that $(x,y) \in R^\mathcal{J}$ and $y \notin A_3^\mathcal{I}$.

Note that, given a model $\mathcal{I}$, if some element $x \in (A_1^\mathcal{I} \cap (\exists R.A_2)^\mathcal{J}) \setminus (\forall R.A_3)^\mathcal{J}$ then there always exists some $y \in \Delta^\mathcal{J}$ such that $(x,y) \in R^\mathcal{J}$ and $y \notin A_3^\mathcal{I}$.

We proceed to verify that $\mathcal{J}$ is indeed a model of $\mathcal{O}_\varphi$. To do so, we prove that all types of axioms in $\mathcal{O}_\varphi$ are entailed by $\mathcal{J}$. The different types of axioms are as follows.

1. $A_1 \cap \ldots \cap A_n \subseteq B \in \mathcal{O}_\varphi \cap \mathcal{O}$. Let $x \in (A_1 \cap \ldots \cap A_n)^\mathcal{J}$. This implies $x \in (A_1 \cap \ldots \cap A_n)^\mathcal{I}$ by the definition of $\mathcal{J}$. Since $\mathcal{I}$ is a model we have that $x \in B^\mathcal{I}$. Then $x \in B^\mathcal{J}$ also by the definition of $\mathcal{J}$.

2. $A_1 \cap \ldots \cap A_n \subseteq B \in \mathcal{O}_\varphi \setminus \mathcal{O}$. Then $A_1 \cap \ldots \cap A_n \subseteq B$ is of the form $C_1 \cap X_\alpha \subseteq Y_\alpha$ where $\alpha = C_1 \cap \exists R.C_2 \cap \forall R.C_3 \subseteq B$. Let $x \in C_1^\mathcal{J} \cap X_\alpha^\mathcal{J}$. Then $x \in C_1^\mathcal{J} \cap \exists R.C_2^\mathcal{J} \cap \forall R.C_3^\mathcal{J}$ by the definition of $\mathcal{J}$. Then $x \in Y_\alpha^\mathcal{J}$ also by the definition of $\mathcal{J}$.

3. $R \subseteq S \in \mathcal{O}_\varphi \cap \mathcal{O}$. Let $(x,y) \in R^\mathcal{J}$. This implies $(x,y) \in R^\mathcal{I}$ by the definition of $\mathcal{J}$. Since $\mathcal{I}$ is a model we have that $(x,y) \in S^\mathcal{I}$. Then $(x,y) \in S^\mathcal{J}$ also by the definition of $\mathcal{J}$.

4. $R \subseteq S \in \mathcal{O}_\varphi \setminus \mathcal{O}$. Then $R \subseteq S$ is of the form $Z_\alpha \subseteq V$ where $\alpha = A_1 \cap \exists V.A_2 \cap \forall V.A_3 \subseteq B \in \mathcal{O}$. Let $(x,y) \in Z_\alpha^\mathcal{J}$. Then $(x,y) \in V^\mathcal{J}$ by the definition of $\mathcal{J}$.

5. $R^\mathcal{I} \subseteq S \in \mathcal{O}_\varphi$. Let $(x,y) \in R^\mathcal{J}$. This implies $(x,y) \in R^\mathcal{I}$ by the definition of $\mathcal{J}$. Since $\mathcal{I}$ is a model and $R^\mathcal{I} \subseteq S \in \mathcal{O}$ we have that $(x,y) \in (R^\mathcal{I})^\mathcal{J}$ and $(y,x) \in S^\mathcal{J}$. Then $(y,x) \in S^\mathcal{J}$ also by the definition of $\mathcal{J}$.

6. $R \circ V \subseteq S \in \mathcal{O}_\varphi$. Let $(x,z) \in R^\mathcal{J}$ and $(z,y) \in V^\mathcal{J}$. Then $(x,z) \in R^\mathcal{J}$ and $(z,y) \in V^\mathcal{J}$ by the definition of $\mathcal{J}$. Since $\mathcal{I}$ is a model and $R \circ V \subseteq S \in \mathcal{O}$ we have that $(x,y) \in S^\mathcal{J}$. Then $(x,y) \in S^\mathcal{J}$ also by the definition of $\mathcal{J}$.

7. $\exists R.A \subseteq B \in \mathcal{O}_\varphi \cap \mathcal{O}$. Let $(x,y) \in R^\mathcal{J}$ and $y \in A^\mathcal{J}$. Then $(x,y) \in R^\mathcal{J}$ and $y \in A^\mathcal{J}$ by the definition of $\mathcal{J}$. Since $\mathcal{I}$ is a model and $\exists R.A \subseteq B \in \mathcal{O}$ we have that $x \in B^\mathcal{I}$. Then $x \in B^\mathcal{J}$ also by the definition of $\mathcal{J}$.

8. $\exists R.A \subseteq B \in \mathcal{O}_\varphi \setminus \mathcal{O}$. Two cases arise:
   - $\exists R.A \subseteq B$ is of the form $\exists S.A_2 \subseteq X_\alpha$ where $\alpha = A_1 \cap \exists S.A_2 \cap \forall S.A_3 \subseteq B \in \mathcal{O}$. Let $(x,y) \in S^\mathcal{J}$ and $y \in A_2^\mathcal{J}$. Then $x \in (\exists S.A_1)^\mathcal{J}$ and $x \in X_\alpha^\mathcal{J}$ by the definition of $\mathcal{J}$. 

13. \( \exists R.A \subseteq B \) is of the form \( \exists Z_{\alpha}.A_{3} \subseteq C \) where \( \alpha = A_{1} \land \exists S.A_{2} \land \forall S.A_{3} \subseteq C \in O \). Let \( (x, y) \in Z_{\alpha}^{J} \) and \( y \in A_{3}^{J} \). Then, by the definition of \( J \), \( x \in A_{1}^{J} \land (\exists S.A_{2})^{J} \land (\forall S.A_{3})^{J} \). Since \( I \) is a model we have that \( x \in C^{J} \).

Consequently, \( x \in C^{J} \) by the definition of \( J \).

9. \( \exists R.\text{Self} \subseteq B \in O_{\forall} \). Let \( (x, x) \in R^{J} \). Then \( (x, x) \in R^{J} \) by the definition of \( J \). Since \( I \) is a model and \( \exists R.\text{Self} \subseteq B \in O \) we have that \( x \in B^{J} \). Then \( x \in B^{J} \) also by the definition of \( J \).

10. \( A \subseteq \exists R.B \in O_{\forall} \cap O_{\forall} \). Let \( x \in A^{J} \) by the definition of \( J \). Since \( I \) is a model we have that there is some \( y \in \Delta^{J} \) such that \( (x, y) \in R^{J} \) and \( y \in B^{J} \). Then there is some \( y \) such that \( (x, y) \in R^{J} \) and \( y \in B^{J} \) also by the definition of \( J \).

11. \( A \subseteq \exists R.B \in O_{\forall} \setminus O_{\forall} \). Then \( A \subseteq \exists R.B \) is of the form \( Y_{\alpha} \subseteq \exists Z_{\alpha} \cdot \top \). Let \( x \in Y_{\alpha}^{J} \). Then \( (x, y) \in Z_{\alpha} \) for some \( y \) by the definition of \( J \).

12. \( A \subseteq \exists R.\text{Self} \subseteq O_{\forall} \). Let \( x \in A^{J} \). Then \( x \in A^{J} \) by the definition of \( J \). Since \( I \) is a model and \( A \subseteq \exists R.\text{Self} \subseteq O \) we have that \( (x, x) \in R^{J} \). Then \( (x, x) \in R^{J} \) also by the definition of \( J \).

13. \( A \subseteq \{ b \} \subseteq O_{\forall} \). Let \( x \in A^{J} \). Then \( x \in A^{J} \) by the definition of \( J \). Since \( I \) is a model and \( A \subseteq \{ b \} \subseteq O \) we have that \( x \in \{ b \}^{J} \). Then \( x \in \{ b \}^{J} \) also by the definition of \( J \).

14. \( \{ a \} \subseteq B \subseteq O_{\forall} \). Let \( x \in \{ a \}^{J} \). Then \( x \in \{ a \}^{J} \) by the definition of \( J \). Since \( I \) is a model and \( \{ a \} \subseteq B \subseteq O \) we have that \( x \in B^{J} \). Then \( x \in B^{J} \) also by the definition of \( J \).

15. \( \text{ran}(R) \subseteq B \subseteq O_{\forall} \). Let \( (x, y) \in R^{J} \). Then \( (x, y) \in R^{J} \) by the definition of \( J \). Since \( I \) is a model and \( \text{ran}(R) \subseteq B \subseteq O \) we have that \( x \in B^{J} \). Then \( x \in B^{J} \) also by the definition of \( J \).

16. \( A \subseteq 1R.B \subseteq O_{\forall} \). Let \( z \in A^{J} \), \( \{ (z, x), (z, y) \} \subseteq R^{J} \) and \( \{ x, y \} \subseteq B^{J} \). This implies \( z \in A^{J} \), \( \{ (z, x), (z, y) \} \subseteq R^{J} \) and \( \{ x, y \} \subseteq B^{J} \) by the definition of \( J \). Then \( x = y \) since \( I \) is a model.

Note that since \( I \) is a model we have that \( x \in \top^{J} \) and \( x \not\in \bot^{J} \) for every \( x \in \Delta^{J} \). Hence \( x \in \top^{J} \) and \( x \not\in \bot^{J} \) for every \( x \in \Delta^{J} \). The semantics of nominals are also enforced by definition.

We now show that every model \( J \) of \( O_{\forall} \) is a model \( I \) of \( O \). Not that for every axiom \( \alpha \in O \) that is not of the form \( A_{1} \land \exists R.A_{2} \land \forall R.A_{3} \subseteq B \) we have that \( I \models \alpha \) since \( \alpha \in O_{\forall} \). Hence, it suffices to show that all axioms of the form \( A_{1} \land \exists R.A_{2} \land \forall R.A_{3} \subseteq B \) are indeed entailed by \( I \).

Let \( \alpha = A_{1} \land \exists R.A_{2} \land \forall R.A_{3} \subseteq B \subseteq O \) and \( x \in A_{1}^{J} \land (\exists R.A_{2})^{J} \land (\forall R.A_{3})^{J} \). Then \( x \in A_{1}^{J} \land (\exists R.A_{2})^{J} \land (\forall R.A_{3})^{J} \). Note that \( \{ \exists R.A_{2} \subseteq X_{\alpha}, A_{1} \land X_{\alpha} \subseteq Y_{\alpha}, Y_{\alpha} \subseteq \exists Z_{\alpha} \cdot \top, Z_{\alpha} \subseteq R, \exists Z_{\alpha} . A_{3} \subseteq B \} \). Since \( J \) is a model, we have that \( x \in X_{\alpha} \cap Y_{\alpha} \) and \( (x, y) \in Z_{\alpha} \cap R^{J} \) for some \( y \). Since \( x \in (\forall R.A_{2})^{J} \) we have \( y \in A_{2}^{J} \). Thus, \( x \in B^{J} \). Since \( I = J \), \( x \in B^{J} \) and \( I \models \exists R.A_{1} \land \forall R.A_{2} \subseteq B \).

Note that solving other reasoning tasks for \( \mathcal{FL}^{++} \) and Horn-\textbf{SROIQ} ontologies can be reduced to checking satisfiability. Therefore, our rewriting can also be used to solve other tasks such as instance retrieval or classification.
4 OWL Syntax Extension

We propose an inclusion of the witnessed universal construct into OWL 2 through several changes on the grammars of the different OWL 2 syntaxes. Before we proceed, however, note that the transformation formulated in Section 3 was defined for axioms with witnessed universal of the form $A_1 \cap \exists R.A_2 \cap \forall R.A_3 \sqsubseteq B$ where $R, A_1, A_2, A_3$ and $B$ are all atomic. This is nevertheless not a strict limitation since arbitrary OWL 2 axioms in which such a witnessed universal occurs within a subexpression and some of $R, A_1, A_2, B$ are not atomic can still be normalized so that witnessed universals only occur in axioms of the form either $A_1 \cap \exists R.A_2 \cap \forall R.A_3 \sqsubseteq B$ where $R, A, A_1, A_2, A_3, B$ are all atomic. This normalization is a simple variant of the standard structural transformation that iteratively introduces definitions for non-atomic subexpressions in the original axioms.

More importantly, this flexibility affords us to consider extending OWL 2 syntax with witnessed universals as a type of class expression, instead of having to define a new type of OWL 2 axiom. The new syntactic element for witnessed universal we shall present in this section is first and foremost just as a syntactic shortcut for the corresponding OWL 2 class expression that uses conjunction, existential quantification, and universal quantification. Obviously, universal quantification is not allowed in the tractable OWL 2 EL profile. With the result from Section 3 we can now incorporate some form of universal quantification via the new syntactic element, which we shall define in the rest of this section.

4.1 OWL 2 Functional-Style Syntax Modification

We start with the modification on the grammar of OWL 2 functional-style syntax in Section 8.2 of [10]. Here, we introduce a new nonterminal symbol ObjectSomeAllValuesFrom to represent a witnessed universal as a new type of object property restrictions. Concretely, we first add the following production rule to the grammar:

ObjectSomeAllValuesFrom ::= 'ObjectSomeAllValuesFrom' '(' ObjectPropertyExpression ClassExpression ClassExpression ')'
The \textbf{ObjectSomeAllValuesFrom} production rule above allows one to express an object property restriction \texttt{ObjectSomeAllValuesFrom( OPE CE\textsubscript{1} CE\textsubscript{2} )}, which is a syntactic shortcut for the class expression

\[
\text{ObjectIntersectionOf}( \text{ObjectSomeValuesFrom}( OPE CE\textsubscript{1} ) \text{ObjectAllValuesFrom}( OPE CE\textsubscript{2} ) )
\]

where both instances of the non-terminal \texttt{OPE} map to the same object property. As an example, one can write axiom \cite{ng2010} from Section 1 using the OWL 2 functional-style syntax as follows:

\[
\text{SubClassOf}( \text{ObjectIntersectionOf}( a:Pizza \text{ObjectSomeAllValuesFrom}( a:hasTopping a:VegTopping a:VegTopping ) ) a:VegPizza )
\]

4.2 OWL 2 Manchester Syntax Modification

For the OWL 2 Manchester syntax \cite{ng2010}, we only need to modify the production rule for \texttt{restriction} into the rule below, using a new reserved word \texttt{someall}. As in the functional-style syntax, the expression ( \texttt{P someall C D} ) is a syntactic shortcut to the expression: ( \texttt{P some C} ) and ( \texttt{P only D} ).

\[
\text{restriction} ::= \text{objectPropertyExpression} \text{'some'} \text{ primary} \\
| \text{objectPropertyExpression} \text{'only'} \text{ primary} \\
| \text{objectPropertyExpression} \text{'value'} \text{ individual} \\
| \text{objectPropertyExpression} \text{'Self'} \\
| \text{objectPropertyExpression} \text{'min'} \text{ nonNegativeInteger} [ \text{ primary} ] \\
| \text{objectPropertyExpression} \text{'max'} \text{ nonNegativeInteger} [ \text{ primary} ] \\
| \text{objectPropertyExpression} \text{'exactly'} \text{ nonNegativeInteger} [ \text{ primary} ] \\
| \text{dataPropertyExpression} \text{'some'} \text{ dataPrimary} \\
| \text{dataPropertyExpression} \text{'only'} \text{ dataPrimary} \\
| \text{dataPropertyExpression} \text{'value'} \text{ literal} \\
| \text{dataPropertyExpression} \text{'min'} \text{ nonNegativeInteger} [ \text{ dataPrimary} ] \\
| \text{dataPropertyExpression} \text{'max'} \text{ nonNegativeInteger} [ \text{ dataPrimary} ] \\
| \text{dataPropertyExpression} \text{'exactly'} \text{ nonNegativeInteger} [ \text{ dataPrimary} ] \\
| \text{objectPropertyExpression} \text{'someall'} \text{ primary primary}
\]

Translation from Manchester syntax to functional-style syntax (and back) is straightforward as in Section 4.2 and 4.3 of \cite{ng2010}. In particular, we add the following row to the second table in Section 4.2 of the aforementioned reference.
### 4.3 Mapping to RDF Graphs in Turtle

We add the witnessed universal construct to the mappings from functional-style syntax to RDF graphs in triple notation (Turtle), whose original document is given in [12]. For brevity, we do not directly specify the OWL/XML and RDF/XML serializations of witnessed universals, and simply assume that such serializations are straightforward to obtain from the triple notation.

To add the witnessed universal construct to the mappings, we first add the following row to the mapping from functional-style syntax to Turtle in Table 1 of [12].

<table>
<thead>
<tr>
<th>Element E of the Structural Specification</th>
<th>Triples Generated in an Invocation T(E)</th>
<th>Main Node of T(E)</th>
</tr>
</thead>
<tbody>
<tr>
<td>ObjectSomeAllValuesFrom( OPE CE₁ CE₂ )</td>
<td>:x rdf:type owl:Restriction .</td>
<td>:x</td>
</tr>
<tr>
<td></td>
<td>:x owl:onProperty T(OPE) .</td>
<td></td>
</tr>
<tr>
<td></td>
<td>:x owl:someAllValuesFrom T(SEQ CE₁ CE₂) .</td>
<td></td>
</tr>
</tbody>
</table>

In the reverse mapping from Turtle to functional-style syntax, we add the following row to Table 13 in [12].

<table>
<thead>
<tr>
<th>If G contains this pattern...</th>
<th>...then CE(_x) is set to this class expression</th>
</tr>
</thead>
<tbody>
<tr>
<td>:x rdf:type owl:Restriction .</td>
<td>ObjectSomeAllValuesFrom( OPE(y) CE(z₁) ) CE(z₂) )</td>
</tr>
<tr>
<td>:x owl:onProperty y .</td>
<td></td>
</tr>
<tr>
<td>:x owl:someAllValuesFrom T(SEQ z₁ z₂) .</td>
<td></td>
</tr>
</tbody>
</table>

### 4.4 OWL 2 EL Syntax Modification

According to the formal grammar of OWL 2 EL (Section 2.2 in [9]), both of the production rules for subClassExpression and superClassExpression produce the same set of class expression via the nonterminal ClassExpression. The result in Section 3 however, implies that witnessed universal can only appear as a subclass expression in a class inclusion axiom in order to be included to OWL 2 EL profile. This means that the production rules for subClassExpression and superClassExpression need to produce different set of class
expressions, resulting in the following modified rules.

\[
\text{subClassExpression} := \text{Class} \mid \text{subObjectIntersectionOf} \mid \text{ObjectOneOf} \mid \\
\text{subObjectSomeValuesFrom} \mid \text{ObjectHasValue} \mid \text{ObjectHasSelf} \mid \\
\text{ObjectSomeAllValuesFrom} \mid \text{DataSomeValuesFrom} \mid \text{DataHasValue}
\]

\[
\text{subObjectIntersectionOf} := \text{ObjectIntersectionOf} \left( \text{subClassExpression} \ \text{subClassExpression} \ \{ \text{subClassExpression} \ \} \ \right)'
\]

\[
\text{subObjectSomeValuesFrom} := \text{ObjectSomeValuesFrom} \left( \text{ObjectPropertyExpression} \ \text{subClassExpression} \right)'
\]

\[
\text{ObjectSomeAllValuesFrom} := \text{ObjectSomeAllValuesFrom} \left( \text{ObjectPropertyExpression} \ \text{subClassExpression} \ \text{subClassExpression} \ \right)'
\]

\[
\text{superClassExpression} := \text{Class} \mid \text{superObjectIntersectionOf} \mid \text{ObjectOneOf} \mid \\
\text{superObjectSomeValuesFrom} \mid \text{ObjectHasValue} \mid \text{ObjectHasSelf} \mid \\
\text{DataSomeValuesFrom} \mid \text{DataHasValue}
\]

\[
\text{superObjectIntersectionOf} := \text{ObjectIntersectionOf} \left( \text{superClassExpression} \ \text{superClassExpression} \ \{ \text{superClassExpression} \ \} \ \right)'
\]

\[
\text{superObjectSomeValuesFrom} := \text{ObjectSomeValuesFrom} \left( \text{ObjectPropertyExpression} \ \text{superClassExpression} \right)'
\]

\[
\text{ObjectSomeAllValuesFrom} := \text{ObjectSomeAllValuesFrom} \left( \text{ObjectPropertyExpression} \ \text{superClassExpression} \ \text{superClassExpression} \ \right)'
\]

Notice that the difference between the production rules for \text{subClassExpression} and \text{superClassExpression} only lies on the introduction of \text{ObjectSomeAllValuesFrom}. On the other hand, the production rules for \text{EquivalentClasses} and \text{DisjointClasses} axioms need not be changed, i.e., they still use the original production rule for \text{ClassExpression}.

5 Conclusions

While universal quantification is, in general, prohibited in \(\mathcal{EL}^{++}\) and \(\mathcal{SROIQ}\), we show that an intuitively rather appealing form of it, witnessed universal quantification, can be added to both of these languages without jeopardizing their pleasant computational properties. In particular, we show that their left-hand side versions can be rewritten into the base languages.

We also provided a suggestion for an OWL syntax extension which could be used as a basis for tool support for the new construct.
