A Better Uncle For OWL

Nominal Schemas for Integrating Rules and Ontologies

ABSTRACT
We propose a description-logic style extension of OWL 2 with nominal schemas which can be used like “variable nominal classes” within axioms. This feature allows ontology languages to express arbitrary DL-safe rules (as expressive in SWRL or RIF) in their native syntax. We show that adding nominal schemas to OWL 2 does not increase the worst-case reasoning complexity, and we identify a novel tractable language SROIQ that is versatile enough to capture the lightweight languages OWL EL and OWL RL.

Web Ontology Language, Description Logic, SROIQ, Semantic Web Rule Language, Datalog, tractability

1. INTRODUCTION
Despite significant recent progress, the search for a satisfactory integration of ontologies and rules for the Semantic Web is still ongoing [17, 23]. After the publication of the 2004 W3C Recommendation for the Web Ontology Language OWL [29], discussion of the problem centered on the uncle rule

\[ \text{brotherOf}(x,y) \land \text{parentOf}(y,z) \rightarrow \text{uncleOf}(x,z), \]

which is easy to state using a simple rule language such as Datalog, but which cannot be modeled at all in the 2004 version of OWL. From the perspective of OWL design criteria, a core difficulty in allowing unrestricted Datalog rules along with OWL axioms is that it leads to undecidability of reasoning in the resulting combined language.

Subsequently, a significant body of work has developed, investigating the integration of description logics (DLs) [1], which form the basis for OWL, and rule languages (typically Datalog). Conceptually, one can distinguish two approaches.

On the one hand, description logics have been extended with additional “description-logic-style” expressive features which make it possible to express certain types of rules. OWL 2 [36], the 2009 revision of the OWL W3C Recommendation, in fact can express the uncle rule mentioned above. By combining new features of OWL 2, many rules with a tree-shaped body can be expressed indirectly [26]. Decidability is nevertheless retained. Many rules, however, such as

\[ \text{hasParent}(x,y) \land \text{hasParent}(x,z) \land \text{married}(y,z) \rightarrow C(x) \] (1)

which defines a class C of children whose parents are married, are still not expressible.

On the other hand, there are approaches of a hybrid nature, in the sense that both OWL axioms and rules are syntactically allowed in ontologies, and a combined formal semantics defines how the hybrid language is to be understood. As already mentioned, such a combination generally leads to undecidability. This is the case for the Semantic Web Rule Language SWRL [19, 20], which is the most straightforward rule extension of OWL, and for the combination of OWL DL ontologies and the Rule Interchange Format RIF (even when restricted to RIF Core) [4, 11]. A prominently discussed idea for retaining decidability is to restrict the applicability of rules to named individuals, i.e., to logical constants that are explicitly mentioned in the ontology. Rules that are understood in this sense are called DL-safe, and the combination of OWL DL and DL-safe rules is indeed decidable [19, 33].

A generalization of DL-safe rules has been introduced in [27] in the form of DL-safe variables, as part of the definition of the tractable rule language ELP. Rather than restricting all variables in a (DL-safe) rule to binding only to known individuals, DL-safe variables allow the ontology engineer to explicitly specify the variables to be treated this way. This approach was subsequently generalized to obtain DL+safe Rules as a class of expressive rule languages for which reasoning is still decidable [23].

In this paper, we expand on the above idea and improve it in several ways. The key technical innovation is the introduction of nominal schemas as new elements of DL syntax. While the semantic intuition behind nominal schemas is the same as that behind DL-safe variables, the difference lies in the fact that DL-safe variables are tied to rule languages, while nominal schemas integrate seamlessly with DL syntax. As a consequence, the language which we propose encompasses DL-safe variable SWRL while staying within the DL/OWL language paradigm. It thus achieves within the DL framework what has hitherto only been achieved by hybrid approaches.
To give an initial example, consider again the rule (1) extended by the axioms

\[ \text{hasParent} (\text{mary}, \text{john}) \]  

(2)

\[ (\exists \text{hasParent}. \exists \text{married}. (\text{john})) (\text{mary}) \]  

(3)

Axiom (2) asserts that John is a parent of Mary, while axiom (3) states that Mary belongs to the class of individuals with some (unnamed) parent who is married to John. Using a first-order logic semantics as in SWRL, rule (1) would thus entail that Mary belongs to the class \( C \). Interpreting rule (1) as DL-safe, however, does not allow this conclusion, since John’s spouse is not named by any constant in the ontology. To retain the conclusion, one can weaken this restriction to require only \( z \) to be DL-safe, while \( x \) and \( y \) can still take arbitrary values. This is possible in the rule-based approach of DL-safe Rules, but cannot be captured in an axiom of existing description logics.

In contrast, using nominal schemas, rule (1) can be expressed as

\[ \exists \text{hasParent}. \{ z \} \cap \exists \text{hasParent}. \exists \text{married}. \{ z \} \subseteq C. \]  

(4)

The desired conclusion again follows. The expression \( \{ z \} \) is a nominal schema, which is to be read as a \textit{variable nominal} that can only represent nominals (i.e., \( z \) binds to known individuals), where the binding is the same for all occurrences of the nominal schema in an axiom.

The main contributions of this paper are as follows:

1. We introduce nominal schemas as a new general constructor for description logics, denoted by the letter \( \nu \) in the DL nomenclature, and define the expressive DL \( \text{SROIQV} \) as an extension of the description logic \( \text{SROIQ} \) underlying OWL 2.

2. We establish the complexity of the common reasoning tasks to be \( \text{N2ExpTime} \)-complete, and thus not harder than OWL 2 regarding worst-case complexity, even in the DL \( \text{SROIQV}(B, x) \) that adds role constructors to \( \text{SROIQ} \).

3. We define \( \text{SROELV}_n(\sqcap, x) \) as a new family of DLs with nominal schemas for which reasoning is possible in polynomial time. In particular, the DL \( \text{SROELV}_3(\sqcap, x) \) is expressive enough to incorporate OWL EL and OWL RL, and to allow restricted semantic interaction between the two.

The expressivity of nominal schemas is also witnessed by the fact that it allows DLs to incorporate arbitrary DL-safe rules, given that concept intersections, existential role restrictions, and the universal (top) role are available. Since such rules preclude polytime reasoning, our tractable DLs \( \text{SROELV}_n(\sqcap, x) \) employ restrictions on the number of certain occurrences of nominal schemas in each axiom.

The close relationship to nominals suggests simple ways of introducing nominal schemas into concrete syntactic forms of OWL 2, e.g., by using the existing syntax for nominal classes with special individual names that represent variables (using some suitable naming convention). This opens a path for introducing this feature into practical applications. While the above worst-case complexity result for \( \text{SROIQV}(B, x) \) may seem encouraging, we believe that the tractable ontology language \( \text{SROELV}_3(\sqcap, x) \) is the most promising candidate for implementations.

The paper is structured as follows. In Section 2 we introduce the syntax and semantics of nominal schemas based on the expressive DL \( \text{SROIQV}(B, x) \). The reasoning complexity of \( \text{SROIQV}(B, x) \) is studied in Section 3. Section 4 and 5 introduce the DLs \( \text{SROELV}_n(\sqcap, x) \) and establish their tractability. In Section 6 we show how DL-safe rules can be expressed with nominal schemas, based on which we can explain the relationship of \( \text{SROELV}_3(\sqcap, x) \) and the tractable profiles of OWL 2 in Section 7. We finish by discussing further related work (Section 8) before presenting our conclusions (Section 9).

2. NOMINAL SCHEMAS FOR OWL

We start by introducing \textit{nominal schemas} as an extension of existing description logics. Our definition of the resulting DL is self-contained but cannot replace introductory texts like [1, 16, 23]. The Web Ontology Language OWL 2 DL is based on the description logic \( \text{SROIQ} \) but we base our extension on the slightly more expressive \( \text{SROIQV}(B, x) \). This DL extends \( \text{SROIQ} \) with boolean constructors (\( \top, \sqcap, \sqcup \)) on simple roles, and with concept products \( C \times D \) that allow the construction of roles as Cartesian products of concepts. It has been shown that this extension does not increase worst-case complexities of reasoning [23, 39].

The DL languages we study are based on a \textit{signature} \( \Sigma = (N_I, N_C, N_R, N_V) \), where \( N_I, N_C, N_R, \) and \( N_V \) are finite and pairwise disjoint sets of \textit{individual names}, \textit{concept names}, \textit{role names}, and \textit{variables}. The set \( N_R \) is partitioned into disjoint sets \( N_R^s \) of \textit{simple role names} and \( N_R^n \) of \textit{non-simple role names}.

For the rest of this paper, we assume that a signature \( \Sigma \) has been fixed and so omit further references to it. The basic building blocks of DLs are concepts and (simple or non-simple) roles:

**Definition 1.** The sets \( C \) of \( \text{SROIQV}(B, x) \) \textit{concepts} and \( R \) (\( R' / R'' \)) of (simple/non-simple) \( \text{SROIQV}(B, x) \) \textit{roles} are defined by the following grammar:

\[ R' := N_R^s | (N_R^s)^- | U | -R' | R' \sqcap R' | R' \sqcup R' | N_C \times N_C \]

\[ R'' := N_R^s | (N_R^s)^- | U | N_C \times N_C \]

\[ R := R' | R'' \]

\[ C := T | \bot | N_C \cup \{ N_I \} \cup \{ N_V \} | -C | C \sqcap C | C \sqcup C | \exists R.C \sqcap \forall R.C \sqcap \exists R'.C \sqsubseteq k R^c.C \sqcup \geq k R^c.C \]

where \( k \) is any non-negative integer. The constant \( U \) is the universal role, and \( \bot \) and \( \top \) are the top and bottom concepts. Concepts \( \{ a \} \) with \( a \in N_I \) are called \textit{nominals}, and concepts \( \{ x \} \) with \( x \in N_V \) are called \textit{nominal schemas}. The set \( R_{C,D,S} = \{ C \times D \mid C, D \in C \} \subseteq R \) is the set of all concept products.

Roles of the form \( R^{-} \) with \( R \in N_R^s \cup N_R^n \) are called \textit{inverse} roles. We define a function \( \text{Inv} : R \rightarrow R \) as follows: For \( R \in N_R^s \), set \( \text{Inv}(R) := R \) and \( \text{Inv}(R^{-}) := R \). For \( R, S \in R \), set \( \text{Inv}(R \sqcap S) := \text{Inv}(R) \sqcap \text{Inv}(S), \text{Inv}(R \sqcup S) := \text{Inv}(R) \sqcup \text{Inv}(S), \text{and Inv}(¬R) := ¬\text{Inv}(R) \). Set \( \text{Inv}(U) := U \) and \( \text{Inv}(C \times D) := D \times C \) for \( C, D \in C \).

\( \text{SROIQV}(B, x) \) knowledge bases are constructed from axioms as follows.

\footnote{The exact relationship is explained in [16]. Here we just note that OWL \textit{classes} and \textit{properties} are called \textit{concepts} and \textit{roles} in DL.
Definition 2. Given roles $R, S_i \in R$, a generalized role inclusion axiom (GRI A) is a statement of the form $S_1 \circ \cdots \circ S_k \subseteq R$, with either $R \notin R^n$, or $k = 1$ and $S_1 \in R^n$. A set of RIA s is regular if there is a strict partial order $\prec$ on $R$ such that

- if $R \notin \{S, \text{Inv}(S)\}$, then $S \prec R$ if and only if $\text{Inv}(S) \prec R$; and
- if every RIA has the form $R \circ R \subseteq R$, $\text{Inv}(R) \subseteq R$, $R \circ S_1 \circ \cdots \circ S_k \subseteq R$, or $S_1 \circ \cdots \circ S_k \subseteq R$, with $R, S_i \in R$ and $S_i \prec R$ for each $i \in \{1, \ldots, k\}$.

An RBox axiom is a RIA. A TBox axiom (or general concept inclusion axiom, GCI) is an expression of the form $C \subseteq D$ where $C, D \in C$. An ABox axiom is any expression of the form $C(a)$ or $R(a, b)$ where $C \in N_C, R \in N_R$, and $a, b \in N_1$. A $\text{SROIQ}V(B_\times, \times)$ axiom is any ABox, TBox, or RBox axiom, and a $\text{SROIQ}V(B_\times, \times)$ knowledge base is a regular set of $\text{SROIQ}V(B_\times, \times)$ axioms.

Some presentations of $\text{SROIQ}$ also include RBox axioms for role characteristics which we omit here as they can already be expressed in $\text{SROIQ}V(B_\times, \times)$ anyway: the empty (bottom) role $E (\equiv \top \subseteq \bot)$, role disjointness $\text{disj}(S_1, S_2)$ ($S_1 \cap S_2 \subseteq E$), asymmetry ($\text{disj}(S, \text{Inv}(S))$), reflexivity ($\top \subseteq S\text{Self}$, $S\text{Self} \subseteq \bot$), irreflexivity ($3S\text{Self} \subseteq \bot$), symmetry ($\text{Inv}(R) \subseteq R$, transitivity ($R \circ R \subseteq R$).

An example of a $\text{SROIQ}V(B_\times, \times)$ TBox axiom has been given as axiom (4) above, where $\{\}$ is a nominal schema. Intuitively, each nominal schema appearing in an axiom is universally quantified, but ranges only over elements that are referred to by an individual name.

Definition 3. An interpretation $I = (\Delta^I, \tau^I)$ consists of a domain of discourse $\Delta^I \neq \emptyset$ and a function $\tau^I$ which maps $N_C, N_R, N_1$ to elements, sets, and relations of $\Delta^I$ as shown in Table 1. A variable assignment $Z$ for an interpretation $I$ is a function $Z : N_V \rightarrow \Delta^I$ such that for each $v \in N_V$, $Z(v) = a^I$ for some $a \in N_1$. For any interpretation $I$, assignment $Z$, and $C(i) \in C, R(i) \in N_R, t(i) \in T$, the function $\tau^I : Z$ is defined as shown in Table 1.

$I$ and $Z$ satisfies a $\text{SROIQ}V(B_\times, \times)$ axiom $\alpha$, written $I, Z \models \alpha$, if the corresponding condition shown in Table 1 holds. $I$ satisfies $\alpha$, written $I \models \alpha$, if $I, Z \models \alpha$ for all variable assignments $Z$ for $I$. $I$ satisfies a $\text{SROIQ}V(B_\times, \times)$ knowledge base $KB$, written $I \models KB$, if $I \models \alpha$ for all $\alpha \in KB$, and $KB$ is satisfiable if such an $I$ exists. The axiom $\alpha$ is entailed by $KB$, written $KB \models \alpha$, if all models of $KB$ are also models of $\alpha$.

The logic $\text{SROIQ}(B_\times)$ is obtained from $\text{SROIQ}V(B_\times, \times)$ by disallowing nominal schemas; concept products are already covered by $\text{SROIQ}(B_\times)$ since they can be simulated using role negations [39]. The logic $\text{SROIQ}$ is in turn obtained from $\text{SROIQ}(B_\times)$ by disallowing boolean role constructors. In Section 6, we show that $\text{SROIQ}(B_\times, \times)$ is also expressive enough to encompass DL-safe rules (and thus DL-safe SWRL and DL-safe RIF-Core).

We note that it is straightforward to introduce nominal schemas into the normative RDF syntax for OWL 2 [37]. One way to do this would be to provide URIs for variables in the OWL namespace, used instead of individuals in owl:oneOf statements (which are used for the RDF syntax for nominals in OWL 2).

3. REASONING WITH $\text{SROIQ}V(B_\times, \times)$

We now show that the standard inferencing problems for $\text{SROIQ}V(B_\times, \times)$ knowledge bases are decidable and have the same worst-case complexity as for $\text{SROIQ}$. Specifically, they are N2EXPTime-complete.

Many common inference problems for DLs require us to check whether a certain axiom or set of axioms is entailed by the given knowledge base. For example, a concept $C$ is subsumed by a concept $D$ if $C \subseteq D$ is entailed. It is well known that such entailment questions can be reduced to checking knowledge base satisfiability, i.e., asking whether some axiom is entailed is the same as asking if some (modified) knowledge base is satisfiable; see [1, 23] for details. Hence we focus on satisfiability checking only.

Reasoning with $\text{SROIQ}V(B_\times, \times)$ knowledge bases can be simplified by first grounding them, i.e., eliminating nominal schemas by replacing them with the (finitely many) nominals that they can represent. Reasoning in the resulting $\text{SROIQ}(B_\times)$ knowledge base is then possible as in [39].

Definition 4. If $\alpha$ is a $\text{SROIQ}V(B_\times, \times)$ axiom, then its grounding $\text{ground}(\alpha)$ is the set of all axioms that can be obtained by uniformly replacing nominal schemas in $\alpha$ with nominals of the given signature. Given a $\text{SROIQ}V(B_\times, \times)$ knowledge base $KB$, $\text{ground}(KB) := \bigcup_{\alpha \in KB} \text{ground}(\alpha)$.

Theorem 1. A $\text{SROIQ}V(B_\times, \times)$ knowledge base $KB$ is satisfiable if and only if $\text{ground}(KB)$ is satisfiable. In particular, checking satisfiability of $\text{SROIQ}V(B_\times, \times)$ knowledge bases is decidable.

Proof. Consider any interpretation $I$ of the signature, which is the same for $KB$ and $\text{ground}(KB)$. For any TBox axiom $C \subseteq D \in KB$ and a variable assignment $Z$ for $I$, it is clear that $I, Z \models C \subseteq D$ if $I \models C' \subseteq D'$ where $C' \subseteq D' \in \text{ground}(KB)$ was obtained from $C \subseteq D$ by replacing each nominal schema $(x)$ with a nominal $(c)$ such that $c^I = Z(x)$. A suitable constant $c$ must exist for $Z$ by Definition 3. Conversely, every uniform replacement of nominal schemas in $C \subseteq D$ corresponds to a choice of $Z$. We conclude that $I \models C \subseteq D$ if $I \models \text{ground}(C \subseteq D)$. Analogous arguments apply to ABox and RBox axioms, showing the first part of the claim. The second part follows as $\text{ground}(KB)$ is a $\text{SROIQ}(B_\times)$ knowledge base, so satisfiability can be checked as in [39].

Intuitively, every $\text{SROIQ}V(B_\times, \times)$ axiom represents an exponential number of $\text{SROIQ}(B_\times)$ axioms that are obtained by grounding. This yields an upper bound for the complexity of reasoning with $\text{SROIQ}V(B_\times, \times)$ that is exponentially larger than that of $\text{SROIQ}(B_\times)$, i.e. N3EXPTime. We now prove that this result can be refined to obtain an N2EXPTime upper complexity bound, showing that this reasoning problem must be N2EXPTime-complete. To accomplish this, we extend the original proof for the worst-case complexity of $\text{SROIQ}$ [22].

We first recall the complexity proof of [22], including its extension to $\text{SROIQ}(B_\times)$ [39]. The proofs are based on an exponential reduction of DL knowledge bases to theorems of $C^2$, the two-variable fragment of first-order logic with counting quantifiers, for which satisfiability can be checked in NEXPTime [38]. The reduction proceeds in three steps:

1. axioms are transformed into a simplified normal form,
2. complex RIA s are eliminated, and
3. the resulting axioms are expressed as formulæ of $C^2$.

| TBox axiom            | $C \subseteq D$      | $C^I \subseteq D^I, Z^I$                                                |
| RBox axiom (RIA)      | $R \subseteq S$      | $R^I \subseteq S^I, Z^I$                                               |
|                       | $R_1 \circ \cdots \circ R_n \subseteq S$ | $R_1^I \circ \cdots \circ R_n^I \subseteq S^I, Z^I$ |

where $R(i) \in N^R$, $S_1 \in R^c$, and $C \equiv D$ is short for $(C \subseteq D, D \subseteq C)$. This normalization can be done in linear time; see [39] for details. The only axioms that are not readily expressed in $C^I$ are complex RIAs. They are eliminated next, with exponential effort.

Step (2) applies a technique from [12] using nondeterministic finite automata (NFA) to represent RIAs that entail non-simple roles. Suitable NFAs for SROIQ were defined in [18, 21]. We do not repeat the details of this construction here, and merely quote the essential results. Proofs for the following facts can be found in [18] and the accompanying technical report.

**FACT 1.** Consider a SROIQ knowledge base $KB$. For each (possibly inverse) role $R \in N^R$, there is an NFA $A_R$ over the alphabet $N^R$ such that the following holds for every model $\mathcal{I}$ of $KB$, and for every word $S_1 \ldots S_n$ accepted by $A_R$:

If $\langle \delta_i, \delta_{i+1} \rangle \in S_i^I$ for all $i = 1, \ldots, n$, then $\langle \delta_1, \delta_{n+1} \rangle \in R^I$.

Moreover, let $\prec$ denote a strict linear order that witnesses regularity of $KB$ as required in Definition 2. For each $R \in N^R$, the number of states of $A_R$ is bounded exponentially in the depth of $KB$ that is defined as:

$$\max \{n \mid \text{there are } S_1 \prec \ldots \prec S_n \text{ such that } T_{i_1} \circ \ldots \circ T_{i_{n+1}} \subseteq S_{i+1} \in KB\}$$

It suffices to construct the respective NFA for non-simple roles, and our additional role expressions thus do not interfere with this construction. Now step (2) proceeds by replacing every axiom of the form $A \subseteq \forall R.B$ by the following set of axioms, where $A_R$ is the NFA as introduced above, and $X_q$ are fresh concept names for each state $q$ of $A_R$:

$$A \subseteq X_q$$ $q$ is the initial state of $A_R$

$$X_q \subseteq \forall S.X_{q'} \quad A_R \text{ has a transition } q \rightarrow q'$$

$$X_q \subseteq R \quad q \text{ is a final state of } A_R$$

Moreover, all complex RIAs of the form $S_1 \circ \ldots \circ S_n \subseteq R$ with $n \geq 2$ are deleted. The number of new axioms (and fresh concept names) that are introduced for each axiom of the form $A \subseteq \forall R.B$ is bounded by the sum of the number of states and transitions in $A_R$, and the number of transitions in turn is linear in the number of role names and states. According to Fact 1, the number of axioms introduced for each axiom $A \subseteq \forall R.B$ is exponentially bounded in the depth of
The overall size of the knowledge base after step (2) therefore is bounded by a function that is linear in the size of the knowledge base and exponential in the depth of the knowledge base.

Step (3), finally, is a simple rewriting to $C^2$ that does not increase the size of the knowledge base. To obtain the main result of this section, it suffices to observe that grounding does not increase the depth of the knowledge base:

**Theorem 2.** The problem of deciding satisfiability in $SROIQV(B_s\times)$ KBs is $\text{N2ExpTime}$-complete.

**Proof.** By adopting a result from [23, Proposition 5.2.1], one can show that for each $SROIQV(B_s\times)$ knowledge base $KB$, one can find an equisatisfiable $SROIQ\langle B_s\times \rangle$ knowledge base without $\times$, the size of which is linear in the size of $KB$. Thus assume that $KB$ has no concept products. The depth of $KB$ is only affected by RBox axioms. In the absence of concept products, RBox axioms are not affected by grounding, hence the depth of $\text{ground}(KB)$ is equal to the depth of $KB$.

Since $\text{ground}(KB)$ is in $SROIQ(B_s\times)$, one can apply the transformation steps (1)–(3). This yields a $C^2$ theory $T$ that is equisatisfiable to $\text{ground}(KB)$ [39] and thus to $KB$ (Theorem 1). The size of $T$ is linear in the size of $\text{ground}(KB)$ and exponential in the depth of $KB$. Both measures are exponential in the size of $KB$, and so is $T$. Deciding satisfiability of $T$ can be done in $\text{NExpTime}$ [38], thus deciding satisfiability of $KB$ in $\text{N2ExpTime}$.

$SROIQ\langle B_s\times \rangle$ includes $SROIQ$, for which deciding satisfiability is $\text{N2ExpTime}$-hard [22]. From this, hardness follows. □

4. A TRACTABLE FRAGMENT

The result that reasoning in $SROIQ\langle B_s\times \rangle$ has the same worst-case complexity as $SROIQ$ (and OWL 2) is encouraging, yet we are far from a practical reasoning procedure for this DL. In particular, Theorem 2 is based on a procedure that still takes exponentially longer than the original approach for $SROIQ$, without this affecting the worst-case complexity. In this section, we therefore focus on identifying cases where inferencing is possible in polynomial time. This still leads to a rather expressive tractable DL. Subsequent sections will highlight the relationship to the tractable profiles of OWL 2.

Concretely, we define DLs $SROELV_n(\pi, \times)$ for each integer $n \geq 0$, $n$ restricting the number of “problematic” occurrences of nominal schemas detailed below. The DLs are based on the tractable DL $SROEL(\pi, \times)$, introduced as an extension of OWL EL [24]. In essence, $SROEL(\pi, \times)$ is $SROIQ(B_s)$ restricted to operators $\pi$, $\exists$ (possibly with $\text{Self}$), $\circ$, and some uses of $\times$. To preserve tractability when adding nominal schemas, we must avoid the increase in the number of axioms during grounding, which is exponential in the number of nominal schemas per axiom.

Unfortunately, one cannot reduce the number of nominal schemas by normal form transformations in general, since they represent complex dependencies that cannot be simplified. But there are special cases where nominal schemas on the left-hand side of TBox axioms can be eliminated, or separated using independent axioms. One such case was identified in [27] for the rule language ELP: if the dependencies expressed in a rule body are tree-shaped then the rule can always be reduced to a small set of normalized rules with a limited number of variables in each. For example, a rule body that consists of a conjunction $A(x) \land R(x, z) \land S(x, y) \land B(y) \land T(y, z)$ is not tree-shaped since there are parallel paths $x \xrightarrow{B} z$ and $x \xrightarrow{S} y \xrightarrow{T} z$ in the corresponding dependency structure. In our case, binary predicates are role names, unary predicates are concept names, and constant symbols correspond to nominals. Variables can either be “hidden” in the structure of the DL concept expression, or occur explicitly as nominal schemas (the latter are called DL-safe variables in ELP). For example, the above rule body can be expressed as a concept $A(\top) \land S(\top) \land B(\top) \land T(\top, z)$.

Here, we do not introduce tree-shaped dependency structures as a general mechanism for ensuring that normal form transformations are possible, and merely identify sufficient conditions for which this is the case. This allows us to provide somewhat simpler proofs. An obvious condition that implies tree-shaped dependencies is that a nominal schema occurs only once, and only on the left-hand side of a TBox axiom. As in [27], the tree-shape only refers to variables (DL-safe or not), not to constants, in rule bodies. This means that nominals (our syntax for constants) disconnect a concept’s dependency structure. E.g., if $B$ in the above rule body is replaced by a nominal $\{a\}$, then the concept would be tree-shaped. In such a case, we say that the nominal $\{z\}$ occurs in a safe environment, as defined next.

**Definition 5.** An occurrence of a nominal schema $\{x\}$ in a concept $C$ is safe if $C$ has a sub-concept of the form $\{a\} \sqcap \exists R.D$ for some $a \in N_1$, such that $D$ contains the occurrence of $\{z\}$ but no other occurrence of any nominal schema. In this case, $\{a\} \sqcap \exists R.D$ is a safe environment for this occurrence of $\{x\}$. $S(a, x)$ will sometimes be used to denote an expression of the form $\{a\} \sqcap \exists R.D$ within which $\{x\}$ occurs safely.

A nominal schema $\{x\}$ is safe for a $SROIQV(B_s\times)$ TBox axiom $C \sqsubseteq D$ if $\{x\}$ does not occur in $D$, and at most one occurrence of $\{x\}$ in $C$ is not safe.

**Definition 6.** Let $n \geq 0$. A $SROELV_n(\pi, \times)$ concept is a $SROIQV(B_s\times)$ concept that may contain $\top$, $\bot$, $\sqcap$, $\sqcup$, $\exists$, $\text{Self}$, nominals and nominal schemas, but which does not contain $\sqsubseteq$, $\sqcap$, $\sqcup$, $\forall$, $\forall_k$, and $\exists$. $SROELV_n(\pi, \times)$ roles (simple or non-simple) are $SROIQV(B_s\times)$ roles (simple or non-simple) that may contain $\sqsubseteq$ (for simple roles) and $U$ but no inverse roles, $\sqcap$, or $\sqcap$. A $SROELV_n(\pi, \times)$ TBox axiom is a $SROIQV(B_s\times)$ TBox axiom $\alpha$ that uses $SROELV_n(\pi, \times)$ concepts only, and where at most $n$ nominal schemas are not safe for $\alpha$. An RBox axiom of $SROELV_n(\pi, \times)$ is an RBox axiom of $SROIQV(B_s\times)$ using only $SROELV_n(\pi, \times)$ roles. An ABox axiom of $SROELV_n(\pi, \times)$ is the same as an ABox axiom of $SROIQV(B_s\times)$.

For a knowledge base $KB$ and role $R \in N_R$, let $\text{ran}(R)$ be the set of all concepts $B \in N_C$ for which there is a set of the form $\{R \sqsubseteq R_1, R_1 \sqsubseteq R_2, \ldots, R_{n-1} \sqsubseteq R_n, R_n \sqsubseteq A \times B\} \subseteq KB$ with $n \geq 0$ and $R_0 = R$. $KB$ is a $SROELV_n(\pi, \times)$ knowledge base if $R_1 \circ \cdots \circ R_n \sqsubseteq S$ implies $\text{ran}(S) \subseteq \text{ran}(R_n)$, and $R_1 \sqcap R_2 \sqsubseteq S$ implies $\text{ran}(S) \subseteq \text{ran}(R_1) \cup \text{ran}(R_2)$.

The additional condition using $\text{ran}$ is called admissibility of range restrictions, see [24] for details. As explained below, restricting to at most $n$ non-safe nominal schemas per axiom ensures that at most $|N_1|^n$ axioms are introduced during grounding. We will fix $n$ at a constant small value, so this
increase is polynomial. It is easy to see that axiom (4) is an example of a $\text{SROELV}_1(\land, \times)$ axiom.

5. REASONING WITH $\text{SROELV}_n(\land, \times)$

If $n$ is constant, the problem of checking satisfiability in $\text{SROELV}_n(\land, \times)$ is possible in polynomial time w.r.t. the size of the knowledge base. To show this, we provide a polynomial transformation to the DL $\text{SROEL}(\land, \times)$, which was shown to be tractable in [24].

Let $KB$ be a $\text{SROELV}_n(\land, \times)$ knowledge base. We define a $\text{SROEL}(\land, \times)$ knowledge base ground$^+(KB)$ as follows. The RBox and ABox of ground$^+(KB)$ are the same as the RBox and ABox of $KB$. For each TBox axiom $\alpha = C \subseteq D \in KB$, the following axioms are added to ground$^+(KB)$:

1. For each nominal schema $\{x\}$ safe for $\alpha$, with safe occurrences in environments $S_i(a_i, x)$ for $i = 1, \ldots, l$, introduce a fresh concept name $O_{x, \alpha}$. For every individual $b \in N_I$ in $KB$, ground$^+(KB)$ contains an axiom

$$\exists U.S_i(a_i, b) \subseteq \exists U.(\{b\} \cap O_{x, \alpha}),$$

where $S_i(a_i, b)$ denotes $S_i(a_i, x)$ with $x$ replaced by $b$, and the empty conjunction ($l = 0$) denotes $\top$.

2. A concept $C'$ is obtained from $C$ as follows. Initialize $C' := (a)$ for each nominal schema $\{x\}$ that is safe for $\alpha$: (a) replace all safe occurrences $S(a, x)$ in $C'$ by $\{x\}$; (b) replace the non-safe occurrence (if any) of $\{x\}$ in $C'$ by $O_{x, \alpha}$; (c) set $C' := C' \cap \exists U.O_{x, \alpha}$. After these steps, $C'$ contains only nominal schemas that are not safe for $\alpha$, and neither for $C' \subseteq D$. Now add axioms $\text{ground}(C' \subseteq D)$ to ground$^+(KB)$.

THEOREM 3. Given a $\text{SROELV}_n(\land, \times)$ knowledge base $KB$, the size of ground$^+(KB)$ is exponential in $n$ and polynomial in the size of $KB$.

Proof. The size of the RBox and ABox of ground$^+(KB)$ is linear in the size of $KB$ and does not depend on $n$. If $m$ is the number of individual names in $KB$, then step 1 above introduces at most $mk$ axioms for each axiom $\alpha$ with $k$ nominal schemas. This is polynomial in the size of $KB$. The second step introduces $\text{ground}(C' \subseteq D)$ many axioms, and hence at most $m^m$ axioms for each $\alpha$.

THEOREM 4. A $\text{SROELV}_n(\land, \times)$ knowledge base $KB$ is satisfiable if and only if ground$^+(KB)$ is satisfiable.

Proof. We first introduce some notation to simplify the proof. Let $C$ be a $\text{SROELV}_n(\land, \times)$ concept. A position is a word $p \in \{1, 2\}^*$. The sub-concept $C|p$ of $C$ at position $p$ is defined recursively, where $\varepsilon$ denotes the empty word: $D|\varepsilon := D_1 \cap D_2$; $D_1|p \cdot D_2|p := D_1|p \cdot D_2|p$; $\exists R.D|\varepsilon := \exists R.D$. The positions of $C$ are the positions $p$ for which $C|p$ is defined. Consider an interpretation $\mathcal{I}$ and variable assignment $\mathcal{Z}$ such that $\delta \in C^{\mathcal{I}, \mathcal{Z}}$ for some $\delta \in \Delta^{\mathcal{I}}$. We non-deterministically define witnesses $\delta_\alpha \in \Delta^{\mathcal{I}}$ for all positions $p$ of $C$, such that $\delta_\alpha \in (C|p)^{\mathcal{I}, \mathcal{Z}}$. Set $\delta := \delta_\varepsilon$. For the recursion, assume that $\delta_\alpha$ has been defined. If $C|p = D_1 \cap D_2$, then $\delta_\alpha = \delta_\alpha$ and $\delta_\alpha := \delta_\alpha$. If $C|p = \exists R.D$, then $\delta_\alpha \in (C|p)^{\mathcal{I}, \mathcal{Z}}$ implies that there is some $\varepsilon$ with $(\delta_\alpha, \epsilon) \in \mathcal{I}$ and $\epsilon \in D^{\mathcal{I}, \mathcal{Z}}$. Set $\delta_{\alpha} := \epsilon$. Below, the selection of $\delta_\alpha$ is always assumed to be arbitrary but fixed. To clarify the context, we say that $\delta_\alpha$ is a witness for $\delta \in C^{\mathcal{I}, \mathcal{Z}}$. Intuitively, $\delta_\alpha$ thus witnesses a substructure of $\mathcal{I}$ that satisfies the semantic conditions for $\delta \in C^{\mathcal{I}, \mathcal{Z}}$.

An interpretation $\mathcal{I}$ for ground$^+(KB)$ is $O$-minimal if the following holds for all concept names $O_{x, \alpha}$ introduced in step 1 and all $b \in N_I$ in $KB$: $\mathcal{I} \models O_{x, \alpha}(b)$ if $\exists U.S_i(a_i, b) \neq \emptyset$ (using the notation from step 1). Clearly, every model of $KB$ can be extended to an $O$-minimal interpretation of ground$^+(KB)$. Conversely, if ground$^+(KB)$ is satisfiable, it surely has an $O$-minimal model. Namely, any model can be made $O$-minimal by reducing the extensions of $O_{x, \alpha}$ as required. This does not affect the truth of other axioms, since $O_{x, \alpha}$ only occurs in positive (non-negated) positions in the premise of TBox axioms, reducing its extension makes the premise smaller while not affecting the conclusion.

So the claim can be obtained by showing: the $O$-minimal extension of every model of $KB$ is a model of ground$^+(KB)$, and every $O$-minimal model of ground$^+(KB)$ is a model of $KB$ if we ignore the interpretation of concepts $O_{x, \alpha}$. This can be shown individually for each axiom of $KB$. It is immediate for ABox and RBox axioms.

Now consider a TBox axiom $\alpha = C \subseteq D \in KB$, and the axiom $C' \subseteq D$ constructed in step 2. By the proof of Theorem 1, the models of $C' \subseteq D$ and ground$^+(KB)$ are the same. To complete the proof, we show that an $O$-minimal model satisfies $C \subseteq D$ iff it satisfies $C' \subseteq D$. This is implied by the following property ($\ast$): given an $O$-minimal interpretation $\mathcal{I}$ of ground$^+(KB)$, we find that $\delta \in C^{\mathcal{I}, \mathcal{Z}}$ for some variable assignment $\mathcal{Z}$ if $\delta \in C^{\mathcal{I}, \mathcal{Z}}$, for some variable assignment $\mathcal{Z}$, where assignments in either direction of the claim can be chosen such that $D^{\mathcal{I}, \mathcal{Z}} = D^{\mathcal{I}, \mathcal{Z}}$. Indeed, if $\mathcal{I} \models C \subseteq D$ and $\delta \in C^{\mathcal{I}, \mathcal{Z}}$, then by ($\ast$) we obtain with $\delta \in C^{\mathcal{I}, \mathcal{Z}}$, thus $\delta \in D^{\mathcal{I}, \mathcal{Z}}$, and $\delta \in D^{\mathcal{I}, \mathcal{Z}}$. The reverse direction is similar.

We show both directions of ($\ast$) by induction over the steps used to construct $C'$ from $C$. The claim holds initially when $C = C'$. Now consider the modifications (a)–(c) for one nominal schema $\{x\}$ that is safe for $\alpha$, and let $C_0, C_a, C_b$, and $C_c$ denote $C'$ in its initial state and after each of the steps (a)–(c).

For the "only if" direction, assume $\delta \in C^{\mathcal{I}, \mathcal{Z}}$. We show $\delta \in C^{\mathcal{I}, \mathcal{Z}}$, i.e., we set $\mathcal{Z} := \mathcal{Z}$. Let $S_i(a_i, x)$ be as in step 1. Since all $S_i(a_i, x)$ are sub-concepts of $C_0$ and $C^{\mathcal{I}, \mathcal{Z}} \neq \emptyset$, we can apply our initial construction of witnesses $\delta_\alpha$ to conclude $S_i(a_i, x) \neq \emptyset$ for all $i \in \{1, \ldots, l\}$ and some $b$ with $b^2 \in Z(x)$. As $\mathcal{I}$ satisfies the axioms of step 1 (by $O$-minimality), this shows $\exists U.O^{\mathcal{I}, \mathcal{Z}}.Z = \mathcal{I}$ for $x \in \{1, \ldots, l\}$. Hence $\delta_{S_i(a_i, x)} \in O_{x, \alpha}(b)$ for all $i \in \{1, \ldots, l\}$ so $D^{\mathcal{I}, \mathcal{Z}} \subseteq E^{\mathcal{I}, \mathcal{Z}}$ follows the fact that $\mathcal{I}$ satisfies the axioms of step 1.

For the "if" direction, assume $\delta \in C^{\mathcal{I}, \mathcal{Z}}$. For the concept introduced in (c), we have $\exists U.O^{\mathcal{I}, \mathcal{Z}}.Z = \emptyset$, so $O^{\mathcal{I}, \mathcal{Z}}.Z = \emptyset$, and thus $\exists U.O^{\mathcal{I}, \mathcal{Z}}.Z = \emptyset$. This shows $C^{\mathcal{I}, \mathcal{Z}} = C^{\mathcal{I}, \mathcal{Z}}$. If an occurrence of $x$ at position $p$ in $C_0$ was replaced by $O_{x, \alpha}$ in (b), then set $\varepsilon := \delta_\alpha$, where $\delta_\alpha$ is a witness for $\delta \in C^{\mathcal{I}, \mathcal{Z}}$. Otherwise, if $C_a = C_b$, then select $\varepsilon \in C^{\mathcal{I}, \mathcal{Z}}$ arbitrarily. Define $\mathcal{Z}$ such that $\mathcal{Z}(x) = \varepsilon$ and $\mathcal{Z}(y) = \mathcal{Z}(y)$ for all $y \neq x$. We claim $\delta \in C^{\mathcal{I}, \mathcal{Z}}$. We showed $C^{\mathcal{I}, \mathcal{Z}} = C^{\mathcal{I}, \mathcal{Z}}$ above, and
as x does not occur in C_b, we have C^{x,z}_b = C^{b}_b. Thus δ ∈ C^{x,z}_b. Now consider the witnesses δ_γ for δ ∈ C^{x,z}_b.

It is easy to see that the same elements can be chosen as witnesses for δ ∈ C^{y,z}_b, showing that the latter holds. This follows since ε ∈ {x}^{x,z} (for the sub-concepts replaced in (b)), and since δ_{8(a,s)} = a^z_t ∈ {a^z}_t (for the sub-concepts replaced in (a)).

A knowledge base is unsatisfiable if and only if it entails \{a^i_a\} ⊆ ⊥ for arbitrary a ∈ N_1. This reduces satisfiability testing to instance retrieval (checking if a is an instance of ⊥). Using the polynomial time instance retrieval method for SROEL(Π, x) from [24] together with Theorems 3 and 4, we thus obtain the following result. Hardness for P follows from the hardness of SROEL(Π, x).

**Theorem 5.** If KB is a SROELV_n(Π, x) knowledge base of size s, satisfiability of KB can reduced to instance retrieval w.r.t. a set of Datalog rules of size proportional to s^n and at most four variables per rule. If n is constant, the problem is P-complete.

6. DL-SAFE RULES

As shown here, an interesting feature of nominal schemas is that they can be used to express arbitrary DL-safe rules [33]. These are Datalog rules with unary and binary predicates that are restricted – just like nominal schemas – to apply to domain elements that are represented by individual names.\(^2\) Identifying unary predicates with concept names, binary predicates with role names, constants with individual names, and (DL-safe) variables with the variables in nominal schemas, the syntax of DL-safe rules can be based on a DL signature. As before, we assume the signature \(Σ = (N_1, N_C, N_R, N_V)\) to be fixed and omit explicit references to it. The set of terms \(T\) of \(Σ\) is \(N_1 \cup N_V\). We can now define the syntax and semantics of DL-safe rules.

**Definition 7.** A concept atom is an expression of the form A(t) with t ∈ T and A ∈ N_C \(∪ \{\top, \bot\}\). A role atom is an expression of the form R(s,t) with s,t ∈ T and R ∈ N_R. An atom is a concept or role atom.

If B is a finite and non-empty set of atoms and H is an atom, then \(B \rightarrow H\) is a DL-safe rule. B is called the body, and H is called the head. A DL-safe rule that contains at most n distinct variables is called an n-variable rule.

**Definition 8.** Interpretations \(I\) and variable assignments \(Z\) for DL-safe rules are defined as in Definition 3. An atom F is satisfied by I and Z, written I, Z \models F, if either F = A(t) and t^I,Z \in A\^I,Z, or F = R(s,t) and (s^I,Z, t^I,Z) \in R\^I,Z. A set of atoms B is satisfied by I and Z, written I, Z \models B, if I, Z \models F for all F ∈ B.

I satisfies a DL-safe rule \(B \rightarrow H\), written I \models \(B \rightarrow H\), if for all assignments \(Z\) for I, either I, Z \models H or I, Z \nmodels H. A set of rules is satisfied if all of its elements are. Models, satisfiability, and entailment are defined as in Definition 3.

The above provides a first-order logic semantics for DL-safe rules that is fully compatible with the semantics of SROIQV(\(B_0, x\)) – it uses the same kinds of models. As such, it is meaningful to combine DL-safe rules and DL knowledge bases. The entailment relation is immediate: a DL-safe rule or DL axiom \(Φ\) is entailed by a DL knowledge base KB extended with a set of rules RB if \(Φ\) is satisfied by all interpretations that satisfy both KB and RB.

DL-safe rules can also be used to capture the fragment of the rule language Datalog with predicates of arity at most 2, given that we are interested in the first-order semantics of such Datalog rules.

**Definition 9.** A syntactic transformation \(dl\) from atoms and DL-safe rules to SROIQV(\(B_0, x\)) concepts and TBox axioms is defined as follows. For a unary atom A(t), set dl(A(t)) := ∃U.(∪A \(∩ A\)); for a binary atom R(s,t), set dl(R(s,t)) := ∃U.(∪R \(∩ R\)). For a DL-safe rule \(B \rightarrow H\), set dl(\(B \rightarrow H\)) := \(∃F \in B\) dl(F) \(⊆ \) dl(H). A set of DL-safe rules RB is translated as dl(RB) := \(∪β \rightarrow \) RB dl(\(B \rightarrow H\)).

The function dl transforms rules into SROELV_n(Π, x) TBox axioms, where n is the number of variables in the rule. This ensures that none of the restrictions on simple and non-variable roles, regularity, or admissibility of ranges in SROELV_n(Π, x) are violated. In consequence, dl(KB) is a SROELV_n(Π, x) knowledge base if KB is a set of n-variable rules. Before showing that dl actually preserves the semantics of DL-safe rules, we present a useful lemma.

**Lemma 1.** For an atom F, interpretation \(I\), and variable assignment \(Z\) we have (1) I, Z \models F if and only if dl(F)^I,Z = \(Δ^I\), (2) I, Z \nmodels F if and only if dl(F)^I,Z = ∅.

**Proof.** dl(F) has the form \(∃U,D\), there are only two options; either \(D^I,Z \neq ∅\) and dl(F)^I,Z = \(Δ^I\), or \(D^I,Z = ∅\) and dl(F)^I,Z = ∅. Theorem 2 is obtained as the contrapositive of (1), and we only need to show the latter.

Given dl(F) = \(∃U,D\), it thus suffices to show that I, Z \models F if dl(F)^I,Z = ∅ if and only if dl(F)^I,Z = ∅.

**Proof.** dl(F) = \(∃U,D\), it thus suffices to show that I, Z \models F if dl(F)^I,Z = ∅ if and only if dl(F)^I,Z = ∅.

Thus, dl(F)^I,Z = ∅ is equivalent to \(A^I,Z ⊆ A^I\), which is equivalent to \(A \cap \{\top\} = \emptyset\). For F = R(s,t), the claim is that \((s^I,Z, t^I,Z) ∈ R^I,Z\) is equivalent to \(R\^I,Z \neq ∅\). Both claims are clear from Definitions 3 and 8.

**Theorem 6.** The models of a set RB of DL-safe rules are the same as the models of dl(RB), i.e. RB and dl(RB) are semantically equivalent.

**Proof.** Consider interpretation \(I\), an assignment \(Z\) for \(I\), and a rule \(B \rightarrow H \in RB\) such that dl(\(B \rightarrow H\)) = C_0 ⊆ C_H. Lifting Lemma 1 to sets of atoms B, we find I, Z \nmodels B if dl(C_0)^I,Z = ∅. It is clear that this entails the claim: either I, Z \models H and dl(C_H)^I,Z = ∅, or I, Z \nmodels B and dl(C_B)^I,Z = ∅.

Importantly, this result confirms that nominal schemas are powerful enough to express arbitrary DL-safe rules. The use of nominal schemas, however, in SROIQV(\(B_0, x\)) is more general than the extension of SROIQV(\(B_0\)) with DL-safe rules, since the latter correspond to a special form of SROIQV(\(B_0, x\)) axioms only. Combining Theorem 5 with the observation that dl(RB) is linear in the size of RB, we can state the following:

**Theorem 7.** The problem of deciding whether a knowledge base RB \(∪ KB\) is satisfiable, where RB is a set of n-variable rules with a constant, and KB is a SROELV_n(Π, x) knowledge base, is P-complete.

7. RELATION TO OWL PROFILES

The OWL 2 standard proposes three tractable profiles, i.e., language fragments for which reasoning is possible in (sub)polynomial time [31]. Each of the profiles is closely related to a description logic: OWL EL is contained in SROEL(×,<) [24], OWL RL is an extension of DLP [15], and OWL QL is based on DL-Lite [10]. All OWL 2 profiles include special support for datatypes and concrete data values that we have not considered here. The respective extensions would not lead to any technical difficulty, since datatype literals can be treated like individuals in all profiles.

Here, we note that with certain restrictions (specified below), the profiles OWL RL and OWL EL are contained within SROEL(×,<). The latter also covers most features of OWL QL, but we also note that the typical application areas of this profile are not targeted by our approach.

The relation to OWL EL is obvious: a SROEL(×,<) knowledge base is also a SROELV(×,<) knowledge base, for each n (including n = 3). So this approach subsumes the profile OWL EL without datatypes. Similar to OWL EL, OWL RL disallows any kind of (truly) disjunctive information, but it also excludes all forms of existential quantification. In return, this allows OWL RL to include inverse roles and unrestricted range restrictions which are excluded from OWL EL to preserve tractability. Due to the lack of disjunctive and existential expressions, however, OWL RL axioms can be faithfully represented using DL-safe rules only.

Concretely, OWL RL is based on a Horn Description Logic, the axioms of which can be transformed into a number of normal forms as shown in [25]. As discussed in [23], the TBox and RBox axioms of OWL RL can thus be reduced to the normal forms in Table 2, where A, B, C ⊑ N ⊓ {⊥, ⊤}, R, S ⊑ N, and a ⊑ N. Only three of these axiom types are not in SROELV(×,<). Using DL-safe rules, we can encode A ⊑ ∀R.C into A(x) ⊓ R(x,y) ⊑ C(y), and R ⊑ R ⊓ T into R(x,z) ⊑ T(x,z). For qualified functionality restrictions, an auxiliary “DL-safe equality” role R∞ is encoded with the axiom (x) ⊑ ∃R∞(y) ⊑ ∃U.(x) ⊓ {y}). The axiom A ⊑ ≤1.CR is then represented by the DL-safe rule

\[ A(x), R(x,y), C(x_1), R(x,y_2), C(x_2) → R_{=} (y_1, y_2). \]

Transforming DL-safe rules as in Section 6 and keeping ABox axioms without modification, we thus obtain a simple translation from OWL RL (without datatype-related features) to SROELV(×,<).

OWL QL, finally, is based on DL-Lite, which is designed for its sub-polynomial AC0 data complexity [10]. This also implies that no complex RIA are included, but inverse roles and some forms of existential quantification are allowed. Inverse roles R− can be replaced by new role names Rinv, with the original semantics approximated by DL-safe rules R(x,y) → Rinv(x,y) and Rinv(y,x) → R(y,x). As in the case of OWL RL, this means that certain conclusions are lost, while tractability is preserved. Furthermore, axioms of the form T ⊑ ∃R−.C can be expressed as R ⊑ T × C.

The related restrictions of Definition 6 do not apply in the absence of complex RIAs.

It must be noted that OWL RL axioms that are translated to DL-safe rules are no longer interpreted under their first-order semantics. Entailments of ABox axioms – the main inference task in applications of OWL RL – are preserved, but translated axioms are not semantically equivalent to the original ontology. Indeed, the DL obtained by allowing unions of OWL EL and OWL RL knowledge bases is 2EXPSPACE-complete, as it encompasses all features of Horn-SROIQ [35]. The combination of “DL-safe” OWL RL and OWL EL, in contrast, is still tractable, but does not entail all inferences that the unrestricted combination would.

Also, it should be pointed out that the typical uses of OWL QL for ontology-based querying of large datasets is not supported by SROEL(×,<), at least not as it is by OWL QL. Namely, the low data complexity of OWL QL enables an efficient way of query rewriting that is not available in SROEL(×,<). This limitation cannot be overcome, as AC0 ⊆ P. Conversely, SROEL(×,<) includes many features not available in OWL QL, e.g., role transitivity.

8. RELATED WORK

8.1 Description Logic Rules

The DLs introduced here are closely related to Description Logic Rules, i.e., first-order rule languages that allow sets of rules to be expressed in description logics [23, 26]. As discussed in Section 6, nominal schemas are closely related to variables in DL-safe rules [33].

In [27], ELP was proposed as an extension of DL Rules for $\varepsilon$CL++ with additional DL-safe variables. ELP is more general than the mere union of DL-safe rules and DL Rules, since a single rule can contain some variables that are DL-safe and others that are not. However, the definitions in [27] aim at tractability, and do not allow all uses of DL-safe variables. As discussed in Section 4, safe environments in SROELVn(×,<) are closely related to this approach.

DL-safe variables in ELP do not encompass the unrestricted use of up to n nominal schemas that is permitted in SROELVn(×,<). Like the general use of nominal schemas in SROELQ(×,<), this feature corresponds rather to DL-safe Rules as introduced in [23]. DL-safe Rules are obtained by allowing DL-safe variables to be used in DL Rules, and they can be viewed as a rule version of our approach. Our complexity proofs in Section 5 are based on analogous proofs for DL-safe Rules. In [23], the term “variable nominals” had been proposed for nominal schemas, but no according DL syntax was introduced.

8.2 Existential Rules

Another approach toward integrating ontological modeling and rules are existential rules, that extend Datalog with existential quantifiers in rule heads. This paradigm has attracted much interest recently, and has been studied under a variety of names such as Datalog+−, $\exists$R-rules, and – primarily in the database community – tuple-generating dependencies (TGDs) [2, 3, 6, 7, 8, 9, 13, 14]. As in the combination of rules and DL, reasoning with existential rules is undecidable without further restrictions. A chief interest of many of the above works thus is to establish formalisms for which (conjunctive) query answering is decidable, possibly with a low data complexity. For example, it has been shown that
certain dialects of Datalog+/− capture and extend languages of the DL-Lite family [7, 10].

Although the general motivation of this research is similar, there are significant technical differences to our approach. In particular, none of the above rule languages is expressive enough to capture OWL EL. Moreover, features like cardinality restrictions (or equality constraints) and disjunctive modeling are hardly considered in current works. On the other hand, many decidable fragments of existential rules are highly expressive and exhibit combined complexities of ExpTime and 2ExpTime.

8.3 Description Graphs

Extending DLs with description graphs and rules, as proposed in [30], enables a more explicit way of modeling structures such as those found in the medical sciences and ontologies. As noted in [32], in order to retain decidability, DLs are often designed with some syntactic restrictions which limit their ability to model non-tree-like structures as featured in the uncle example earlier. On the other hand, description graphs allow us to explicitly state relationships between domain elements in the knowledge base which cannot be expressed using standard DL constructs alone. In addition, this approach also allows description graphs to appear as graph atoms in rules, thus allowing conditional statements about the structured objects modeled by the graphs.

In its unrestricted form, extending DLs with description graphs leads to undecidability even under acyclicity conditions. Therefore, some restrictions to prevent rules in DL axioms from interacting with rules appearing in graphs and rules are imposed to retain decidability. Corresponding decidability results for SHOIQ+ and SHOIQV+ have been established. However, we are not aware of any tractable fragments of these formalisms that have been proposed.

Note that SROIQV(B+, ×) knowledge bases also induce graph-like structures due to the presence of nominals and nominal schemas, as evidenced by the fact that they can model DL-safe rules. Yet, neither of the two languages − SROIQV(B+, ×) and DLs extended with description graphs and rules − contains the other. A merging of both approaches is conceivable, but remains to be worked out.

9. CONCLUSIONS AND FUTURE WORK

We have introduced nominal schemas as an extension to DL-based ontology languages, that provides sufficient expressivity to incorporate rule-based modeling into ontologies. In particular, it supports the integration of Web rule languages such as SWRL and RIF with OWL 2 ontologies. An important next step is to realize these ideas for the concrete serialization formats of these languages, and to make the corresponding modeling features available in practice.

The latter task especially includes the implementation of inference algorithms to handle nominal schemas more efficiently. We have shown that our extension does not increase the worst-case complexity of reasoning in OWL 2, and that versatile tractable sub-languages exist. Whether and how these theoretical results can be put into efficient reasoning algorithms is an important research question. Two different approaches seem viable to address this problem. On the one hand, nominal schemas could be implemented by modifying/extending existing OWL 2 implementations that have good support for nominals, such as the OWL 2 reasoner Hermit [34]. This can be accomplished by treating nominal schemas like nominals in the deduction procedure, instantiating them with concrete individuals only when this enables relevant deduction steps. This can be viewed as a method of deferred grounding.

On the other hand, our light-weight ontology languages could be implemented using rule-based procedures as proposed for SROEL [24]. In this setting, nominal schemas can be treated like DL-safe variables. Thus, the rule-based deduction remains similar with the only modification that some variables can only be instantiated with certain constants (the approach in [24] introduces new constant symbols for eliminating existentials, and DL-safe variables are not allowed to represent these auxiliary symbols).

In conclusion, the close relationship to nominals is not merely of syntactic convenience, but prepares a path for the further practical adoption of this feature. Instead of a paradigm shift from ontologies to rules, existing applications could be augmented with bits of rule-based modeling to overcome restrictions of classical DLs. Nominal schemas thus may provide an exceptional opportunity for enhancing the expressive power of ontologies without giving up on established tools, format, or methodologies.
